4.3 ELECTRON AFFINITY

TABLE 4.4 Electron Affinities of Atoms, Molecules, and Radicals

Electron affinity of an atom (molecule or radical) is defined as the energy difference between the lowest (ground) state of the neutral and the lowest state of the corresponding negative ion in the gas phase.

$A(g) + e^- = A^-(g)$

Data are limited to those negative ions which, by virtue of their positive electron affinity, are stable. Uncertainty in the final data figures is given in parentheses. Calculated values are enclosed in brackets.

4.4 ELECTRONEGATIVITY

Electronegativity  $\chi$  is the relative attraction of an atom for the valence electrons in a covalent bond. It is proportional to the effective nuclear charge and inversely proportional to the covalent radius:

$$\chi = \frac{0.31(n + 1 \pm c)}{r} + 0.50$$

where  $n$  is the number of valence electrons,  $c$  is any formal valence charge on the atom and the sign before it corresponds to the sign of this charge, and  $r$  is the covalent radius. Originally the element fluorine, whose atoms have the greatest attraction for electrons, was given an arbitrary electronegativity of 4.0. A revision of Pauling’s values based on newer data assigns 3.90 to fluorine. Values in Table 4.5 refer to the common oxidation states of the elements.

**Source:** L. Pauling, *The Chemical Bond*, Cornell University Press, Ithaca, New York, 1967; L. C. Allen, *J. Am. Chem. Soc.* **111**:9003 (1989); A. L. Allred, *J. Inorg. Nucl. Chem.* **17**:215 (1961).

The greater the difference in electronegativity, the greater is the ionic character of the bond. The amount of ionic character  $I$  is given by:

$$I = 0.46 \left| \chi_A - \chi_B \right| + 0.035(\chi_A - \chi_B)^2$$

The bond is fully covalent when  $(\chi_A - \chi_B) < 0.5$  (and  $I < 6\%$ ).

## 4.5 BOND LENGTHS AND STRENGTHS

### 4.5.1 Atom Radius

The *atom radius* of an element is the shortest distance between like atoms. It is the distance of the centers of the atoms from one another in metallic crystals and for these materials the atom radius is often called the metal radius. Except for the lanthanides (CN = 6), CN = 12 for the elements. The atom radii listed in Table 4.6 are taken mostly from A. Kelly and G. W. Groves, *Crystallography and Crystal Defects*, Addison-Wesley, Reading, Mass., 1970.

TABLE 4.6 Atom Radii and Effective Ionic Radii of Elements

| Element     | Atom<br>radius,<br>pm | Effective ionic radii, pm |                     |       |       |     |
|-------------|-----------------------|---------------------------|---------------------|-------|-------|-----|

\* CN = 11

4.5.2 Ionic Radii

One of the major factors in determining the structures of the substances that can be thought of as made up of cations and anions packed together is ionic size. It is obvious from the nature of wave functions that no ion has a precisely defined radius. However, with the insight afforded by electron

density maps and with a large base of data, new efforts to establish tables of ionic radii have been made, the most successful being those of Shannon and Prewitt. Pertinent references: R. D. Shannon and C. T. Prewitt, *Acta Crystallographica* **B25**:925 (1969); **B26**:1046 (1970) and R. D. Shannon, *Acta Crystallographica* **A32**:751 (1976).

Shannon and Prewitt base their *effective ionic radii* on the assumption that the ionic radius of  $O^{2-}$  (CN 6) is 140 pm and that of  $F^{-}$  (CN 6) is 133 pm. Also taken into consideration is the coordination number (CN) and electronic spin state (HS and LS, high spin and low spin) of first-row transition metal ions. These radii are empirical and include effects of covalence in specific metal-oxygen or metal-fluorine bonds. Older “crystal ionic radii” were based on the radius of  $F^{-}$  (CN 6) equal to 119 pm; these radii are 14–18 percent larger than the effective ionic radii.

### 4.5.3 Covalent Radii

Covalent radii (Table 4.7) are the distance between two kinds of atoms connected by a covalent bond of a given type (single, double, etc.).

**TABLE 4.7** Covalent Radii for Atoms

| Element    | Single-bond<br>radius, pm* | Double-bond<br>radius, pm | Triple-bond<br>radius, pm |
|------------|----------------------------|---------------------------|---------------------------|
| Aluminum   | 126                        |                           |                           |
| Antimony   | 141                        | 131                       |                           |

| 3-covalent nitrogen: RNH <sub>2</sub> , R <sub>2</sub> NH, R <sub>3</sub> N                                       | 147.2(5)        |
| 4-covalent nitrogen: RNH <sub>3</sub> <sup>+</sup> , R <sub>3</sub> N-BX <sub>3</sub>                             | 147.9(5)        |
| In $-\text{C}-\text{N}=-$                                                                                         | 147.5(10)       |
| In aromatic compounds                                                                                             | 143(1)          |
| In conjugated heterocyclic systems (partial double bond)                                                          | 135.3(5)        |
| In $-\text{N}-\text{C}=\text{O}$ (partial double bond)                                                            | 132.2(5)        |
| Double bond: $-\text{C}=\text{N}-$                                                                                | 132             |
| Triple bond (in CN radical, 117.74): $-\text{C}\equiv\text{N}$                                                    | 115.7(5)        |
| Carbon-oxygen                                                                                                     |                 |
| Single bond                                                                                                       |                 |
| Paraffinic and saturated heterocyclic: $-\text{C}-\text{O}-$                                                      | 142.6(5)        |
| Strained, as in epoxides: $\begin{array}{c} \text{C}-\text{C} \\ \diagup \quad \diagdown \\ \text{O} \end{array}$ | 143.5(5)        |
| In aromatic compounds, as Ar-OH                                                                                   | 136(1)          |
| Longer bond in carboxylic acids and esters (HCOOH, 131.2)                                                         | 135.8(5)        |
| In conjugated heterocyclics, as furan                                                                             | 137.1(16)       |
| Double bond                                                                                                       |                 |
| In CO <sup>+</sup>                                                                                                | 111.5           |
| In CO                                                                                                             | 112.8           |
| In CO <sub>2</sub> <sup>+</sup>                                                                                   | 117.7           |
| In HCO                                                                                                            | 119.8(8)        |
| In carbonyls                                                                                                      | 114.5(10)       |
| In aldehydes and ketones                                                                                          | 121.5(5)        |

**TABLE 4.9** Bond Lengths between Carbon and Other Elements (*Continued*)

| Bond type                                                     |                 | Bond length, pm |                 |
|---------------------------------------------------------------|-----------------|-----------------|-----------------|
| Carbon-oxygen ( <i>continued</i> )                            |                 |                 |                 |
| In acyl halides: R—CO—X                                       |                 | 117.1(4)        |                 |
| Shorter bond in carboxylic acids and esters                   |                 | 123.3(5)        |                 |
| In zwitterion forms                                           |                 | 126(1)          |                 |
| In O=C=                                                       |                 | 116.0(1)        |                 |
| In isocyanates: RN=C=O                                        |                 | 117(1)          |                 |
| In conjugated systems, as in partial triple bond: O=C—C≡C     |                 | 121.5(5)        |                 |
| In 1,4-quinones                                               |                 | 115(2)          |                 |
| In metal acetylacetonates                                     |                 | 128(2)          |                 |
| In calcite: CaCO <sub>3</sub>                                 |                 | 129(1)          |                 |
| Carbon-selenium                                               |                 |                 |                 |
| Single bond                                                   |                 |                 |                 |
| Paraffinic: —C—Se—                                            |                 | 198(2)          |                 |
| In presence of fluorine, as in perfluorocompounds: —CF—Se—    |                 | 195(2)          |                 |
| Double bond                                                   |                 |                 |                 |
| In Se=C=, as SeCS and SeCO                                    |                 | 170.9(3)        |                 |
| In CSe radical                                                |                 | 167             |                 |
| Carbon-silicon                                                |                 |                 |                 |
| Alkyl substituent: H <sub>3</sub> C—Si or H <sub>2</sub> C—Si |                 | 187.0(5)        |                 |
| Aryl substituent: aryl—Si                                     |                 | 184.3(5)        |                 |
| Electronegative substituent: R—Si—X                           |                 | 185.4(5)        |                 |
| Carbon-sulfur                                                 |                 |                 |                 |
| Single bond                                                   |                 |                 |                 |
| Paraffinic: —C—S—                                             |                 | 181.7(5)        |                 |
| In presence of fluorine, as in perfluoro compounds: —CF—S—    |                 | 183.5(1)        |                 |
| In heterocyclic systems: partial double bonds                 |                 | 171.8(5)        |                 |
| Double bonds                                                  |                 |                 |                 |
| In S=C; thiophene, S=CR <sub>2</sub>                          |                 | 171(1)          |                 |
| In sulfoxides and sulfones                                    |                 | 180(1)          |                 |
| In presence of second carbon-carbon double bond: S=C—C=C—     |                 | 155.5(1)        |                 |
| In SC radical [in CS <sub>2</sub> <sup>+</sup> , 155.4(5)]    |                 | 153.49(2)       |                 |
| Bond type                                                     | Bond length, pm | Bond type       | Bond length, pm |
| Other elements and carbon                                     |                 |                 |                 |
| C-Al                                                          | 224(4)          | C-Cr            | 192(4)          |

**TABLE 4.11** Bond Dissociation Energies

The bond dissociation energy (enthalpy change) for a bond A—B which is broken through the reaction

is defined as the standard-state enthalpy change for the reaction at a specified temperature, here at 298 K. That is,

$$\Delta H_{298}^{\circ} = \Delta H_{298}^{\circ}(\text{A}) + \Delta H_{298}^{\circ}(\text{B}) - \Delta H_{298}^{\circ}(\text{AB})$$

All values refer to the gaseous state and are given at 298 K. Values of 0 K are obtained by subtracting  $\frac{3}{2}RT$  from the value at 298 K.

To convert the tabulated values to kcal/mol, divide by 4.184.

| Bond                  | $\Delta H_{298}^{\circ}$ ,<br>kJ/mol | Bond                          | $\Delta H_{298}^{\circ}$ ,<br>kJ/mol |

## 4.6 BOND AND GROUP DIPOLE MOMENTS

All bonds between equal atoms are given zero values. Because of their symmetry, methane and ethane molecules are nonpolar. The principle of bond moments thus requires that the CH<sub>3</sub> group moment equal one H—C moment. Hence the substitution of any aliphatic H by CH<sub>3</sub> does not alter the dipole moment, and all saturated hydrocarbons have zero moments as long as the tetrahedral angles are maintained.

**TABLE 4.12** Bond Dipole Moments

| Bond               | Moment, D* | Bond                               | Moment, D* |
|--------------------|------------|------------------------------------|------------|
| H—C                |            | C—N, aliphatic                     | 0.45       |

\* To convert debye units D into coulomb-meters, multiply by  $3.33564 \times 10^{-30}$ .

The group moment always includes the C—X bond. When the group is attached to an aromatic system, the moment contains the contributions through resonance of those polar structures postulated as arising through charge shifts around the ring.

All values for bond and group dipole moments in Tables 4.12 and 4.13 were obtained in benzene solutions.

TABLE 4.13 Group Dipole Moments

| Group                              | Moment, D*   |               |
|------------------------------------|--------------|---------------|
|                                    | Aromatic C—X | Aliphatic C—X |
| C—CH <sub>3</sub>                  | 0.37         | 0.0           |
| C—C <sub>2</sub> H <sub>5</sub>    | 0.37         | 0.0           |
| C—C(CH <sub>3</sub> ) <sub>3</sub> | 0.5          | 0.0           |

\* To convert debye units D into coulomb-meters, multiply by  $3.33564 \times 10^{-30}$ .

4.7 MOLECULAR GEOMETRY

TABLE 4.14 Spatial Orientation of Common Hybrid Bonds

On the assumption that the pairs of electrons in the valency shell of a bonded atom in a molecule are arranged in a definite way which depends on the number of electron pairs (coordination number), the geometrical arrangement or shape of molecules may be predicted. A multiple bond is regarded as equivalent to a single bond as far as molecular shape is concerned.

| Coordination Number | Orbitals Hybridized    | Geometrical Arrangement                                                                                                   | Minimum Radius Ratio |
|---------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------|----------------------|
| 2                   | $sp$<br>$dp$           | Linear                                                                                                                    |                      |
|                     | $p^2$<br>$ds$<br>$d^2$ | Bent (angular)                                                                                                            |                      |

|                     | $d^4sp$                | Trigonal prism                                                                                                            |                      |
| 7                   |                        | One atom above the face of an octahedron, which is distorted chiefly by separating the atoms at the corners of this face. | 0.592                |
| 8                   | $d^4sp^3$              | Square antiprism (dodecahedral)                                                                                           | 0.645                |
|                     |                        | Cube                                                                                                                      | 0.732                |
| 9                   |                        | Formed by adding atoms beyond each of the vertical faces of a right triangular prism.                                     | 0.732                |
| 12                  |                        | Cube-octahedron                                                                                                           | 1.000                |

FIGURE 4.1 Crystal lattice types.

**TABLE 4.15** Crystal Structure

Unit cells of the different lattice types in each system are illustrated in Fig. 4.1.

| System                    | Characteristics                                                                                          | Essential Symmetry                                                                      | Axes in Unit Cell             | Angles in Unit Cell                                                                              |
|---------------------------|----------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|-------------------------------|--------------------------------------------------------------------------------------------------|
| Cubic                     | Three axes equal and mutually perpendicular                                                              | Four threefold axes                                                                     | $a = b = c$                   | $\alpha = \beta = \gamma = 90^\circ$                                                             |
| Tetragonal                | Two equal axes and one unequal axis mutually perpendicular                                               | One fourfold axis                                                                       | $a = b \neq c$                | $\alpha = \beta = \gamma = 90^\circ$                                                             |
| Orthorhombic (or rhombic) | Three unequal axes mutually perpendicular                                                                | Three mutually perpendicular twofold axes, or two planes intersecting in a twofold axis | $a \neq b \neq c$             | $\alpha = \beta = \gamma = 90^\circ$                                                             |
| Hexagonal or trigonal     | Three equal axes inclined at $120^\circ$ with a fourth axis unequal and perpendicular to the other three | One sixfold axis or one threefold axis                                                  | $a = b \neq c$<br>$a = b = c$ | $\alpha = \beta = 90^\circ$ ;<br>$\gamma = 120^\circ$<br>$\alpha = \beta = \gamma \neq 90^\circ$ |
| Monoclinic                | Two axes at an oblique angle with a third perpendicular to the other two                                 | One twofold axis or one plane                                                           | $a \neq b \neq c$             | $\alpha = \beta = 90^\circ$ ;<br>$\gamma \neq 90^\circ$                                          |
| Triclinic                 | Three unequal axes intersecting obliquely                                                                | No planes or axes of symmetry                                                           | $a \neq b \neq c$             | $\alpha \neq \beta \neq \gamma \neq 90^\circ$                                                    |
| Rhombohedral              | Two equal axes making equal angle with each other                                                        |                                                                                         |                               |                                                                                                  |

4.8 NUCLIDES

**TABLE 4.16** Table of Nuclides

Explanation of Column Headings

*Nuclide.* Each nuclide is identified by element name and the mass number  $A$ , equal to the sum of the numbers of protons  $Z$  and neutrons  $N$  in the nucleus. The  $m$  following the mass number (for example,  $^{69m}\text{Zn}$ ) indicates a metastable isotope. An asterisk preceding the mass number indicates that the radionuclide occurs in nature.

*Half-life.* The following abbreviations for time units are employed: y = years, d = days, h = hours, min = minutes, s = seconds, ms = milliseconds, and ns = nanoseconds.

*Natural abundance.* The natural abundances listed are on an “atom percent” basis for the stable nuclides present in naturally occurring elements in the earth’s crust.

*Thermal neutron absorption cross section.* Simply designated “cross section,” it represents the ease with which a given nuclide can absorb a thermal neutron (energy less than or equal to 0.025 eV) and become a different nuclide. The cross section is given here in units of barns (1 barn =  $10^{-24}$  cm<sup>2</sup>). If the mode of reaction is other than  $(n,\gamma)$ , it is so indicated.

*Major radiations.* In the last column are the principal modes of disintegration and energies of the radiations in million electronvolts (MeV). Symbols used to represent the various modes of decay are:

- $\alpha$ , alpha particle emission

$\beta^-$ , beta particle, negatron

$\beta^+$ , positron

$\gamma$ , gamma radiation
- K, electron capture

IT, isomeric transition

x, X-rays of indicated element (e.g., O-x, oxygen X-rays, and the type, K or L)

For  $\beta^-$  and  $\beta^+$ , values of  $E_{\text{max}}$  are listed. Radiation types and energies of minor importance are omitted unless useful for identification purposes. For detailed decay schemes the literature should be consulted.

**TABLE 4.16** Table of Nuclides (*Continued*)

| Element    | A  | Half-life            | Natural abundance, % | Cross section, barns   | Radiation (MeV)                                          |
|------------|----|----------------------|----------------------|------------------------|----------------------------------------------------------|
| Hydrogen   | 1  |                      | 99.985(1)            | 0.332(2)               |                                                          |

4.9 WORK FUNCTION

**TABLE 4.17** Work Functions of the Elements

The work function  $\phi$  is the energy necessary to just remove an electron from the metal surface in thermoelectric or photoelectric emission. Values are dependent upon the experimental technique (vacua of  $10^{-9}$  or  $10^{-10}$  torr, clean surfaces, and surface conditions including the crystal face identification).

| Element | $\phi$ , eV | Element | $\phi$ , eV |
|---------|-------------|---------|-------------|
| Ag      | 4.64        | Eu      | 2.5         |
| Al      | 4.19        | Fe      | 4.65        |
| As      | (3.75)      | Ga      | 4.25        |
| Au      | 5.32        | Ge      | 5.0         |
| B       | (4.75)      | Gd      | 3.1         |
| Ba      | 2.35        | Hf      | 3.65        |
| Be      | 5.08        | Hg      | 4.50        |
| Bi      | 4.36        | In      | 4.08        |
| C       | (5.0)       | Ir      | 5.6         |
| Ca      | 2.71        | K       | 2.30        |
| Cd      | 4.12        | La      | 3.40        |
| Ce      | 2.80        | Li      | 3.10        |
| Co      | 4.70        | Mg      | 3.66        |
| Cr      | 4.40        | Mn      | 3.90        |
| Cs      | 1.90        | Mo      | 4.30        |
| Cu      | 4.70        | Na      | 2.70        |

5.1 SOLUBILITIES

TABLE 5.1 Solubility of Gases in Water

The column (or line entry) headed “ $\alpha$ ” gives the volume of gas (in milliliters) measured at standard conditions (0°C and 760 mm or 101.325 kN · m<sup>-2</sup>) dissolved in 1 mL of water at the temperature stated (in degrees Celsius) and when the pressure of the gas without that of the water vapor is 760 mm. The line entry “A” indicates the same quantity except that the gas itself is at the uniform pressure of 760 mm when in equilibrium with water.

The column headed “1” gives the volume of the gas (in milliliters) dissolved in 1 mL of water when the pressure of the gas plus that of the water vapor is 760 mm.

The column headed “q” gives the weight of gas (in grams) dissolved in 100 g of water when the pressure of the gas plus that of the water vapor is 760 mm.

| Temp.<br>°C | Acetylene |       | Air*                  |                    | Ammonia  |      | Bromine  |      |

**TABLE 5.2** Solubilities of Inorganic Compounds and Metal Salts of Organic Acids in Water at Various Temperatures

Solubilities are expressed as the number of grams of substance of stated molecular formula which when dissolved in 100 g of water make a saturated solution at the temperature stated (°C).

| Substance                        | Formula                                                           | 0°    | 10°   | 20°   | 30°   | 40°   | 60°   | 80°  | 90°  | 100° |
|----------------------------------|-------------------------------------------------------------------|-------|-------|-------|-------|-------|-------|------|------|------|
| <b>Aluminum</b> chloride         | AlCl <sub>3</sub>                                                 | 43.9  | 44.9  | 45.8  | 46.6  | 47.3  | 48.1  | 48.6 |      | 49.0 |

\* Critical point.

**TABLE 5.4** Vapor Pressure of Ice in Millimeters of Mercury

For temperatures from  $-99$  to  $0^{\circ}\text{C}$ .

The values in the table are for ice in contact with its own vapor. Where the ice is in contact with air at a temperature  $t^{\circ}\text{C}$ , this correction must be added:  $\text{Correction} = 20p/(100)(t + 273)$ .

| $t, ^{\circ}\text{C}$ | $p, \text{ mm Hg}$ | $t, ^{\circ}\text{C}$ | $p, \text{ mm Hg}$ | $t, ^{\circ}\text{C}$ | $p, \text{ mm Hg}$ |

**TABLE 5.6** Vapor Pressure of Water

For temperatures from  $-10$  to  $120^{\circ}\text{C}$ .

The values in the table are for water in contact with its own vapor. Where the water is in contact with air at a temperature  $t$  in degrees Celsius, the following correction must be added: Correction (when  $t \leq 40^{\circ}\text{C}$ ) =  $p(0.775 - 0.000\,313t)/100$ ; correction (when  $t > 50^{\circ}\text{C}$ ) =  $p(0.0652 - 0.000\,087\,5t)/100$ .

| $t, ^{\circ}\text{C}$ | $p, \text{ mm Hg}$ | $t, ^{\circ}\text{C}$ | $p, \text{ mm Hg}$ | $t, ^{\circ}\text{C}$ | $p, \text{ mm Hg}$ | $t, ^{\circ}\text{C}$ | $p, \text{ mm Hg}$ |

5.2.1 Vapor-Pressure Equations

Numerous mathematical formulas relating the temperature and pressure of the gas phase in equilibrium with the condensed phase have been proposed. The Antoine equation (Eq. 1) gives good correlation with experimental values. Equation 2 is simpler and is often suitable over restricted temperature ranges. In these equations, and the derived differential coefficients for use in the Hagenmacher and Clausius-Clapeyron equations, the  $p$  term is the vapor pressure of the compound in pounds per square inch (psi), the  $t$  term is the temperature in degrees Celsius, and the  $T$  term is the absolute temperature in kelvins ( $t^{\circ}\text{C} + 273.15$ ).

| Eq. | Vapor-pressure equation               | $dp/dT$                                             | $-[d(\ln p)/d(1/T)]$          |
|-----|---------------------------------------|-----------------------------------------------------|-------------------------------|
| 1   | $\log p = A - \frac{B}{t + C}$        | $\frac{2.303pB}{(t + C)^2}$                         | $\frac{2.303BT^2}{(t + C)^2}$ |
| 2   | $\log p = A - \frac{B}{T}$            | $\frac{2.303pB}{T^2}$                               | $2.303B$                      |
| 3   | $\log p = A - \frac{B}{T} - C \log T$ | $p \left( \frac{2.303B}{T^2} - \frac{C}{T} \right)$ | $2.303B - CT$                 |

Equations 1 and 2 are easily rearranged to calculate the temperature of the normal boiling point:

$$t = \frac{B}{A - \log p} - C \tag{5.1}$$

$$T = \frac{B}{A - \log p} \tag{5.2}$$

The constants in the Antoine equation may be estimated by selecting three widely spaced data points and substituting in the following equations in sequence:

$$\left(\frac{y_3 - y_2}{y_2 - y_1}\right)\left(\frac{t_2 - t_1}{t_3 - t_2}\right) = 1 - \left(\frac{t_3 - t_1}{t_3 + C}\right)$$

$$B = \left(\frac{y_3 - y_1}{t_3 - t_1}\right)(t_1 + C)(t_3 + C)$$

$$A = y_2 + \left(\frac{B}{t_2 + C}\right)$$

In these equations,  $y_i = \log p_i$ .

\* Values are for pure alcohol. Since some commercial antifreezes contain small amounts of water, slightly higher volume concentrations than those given in the table may be required. Antifreezes also contain corrosion inhibitors and other additives to make them function properly as cooling liquids. These affect freezing point slightly and specific gravity to a greater degree. If a protection table is furnished by the manufacturer it should be used in preference to the values given above for the pure substance.

\* Values are for pure alcohol. Since some commercial antifreezes contain small amounts of water, slightly higher volume concentrations than those given in the table may be required. Antifreezes also contain corrosion inhibitors and other additives to make them function properly as cooling liquids. These affect freezing point slightly and specific gravity to a greater degree. If a protection table is furnished by the manufacturer it should be used in preference to the values given above for the pure substance.

† The values are those reported by Bosart and Snoddy (*Jour. Ind. Eng. Chem.*, **19**, 506 (1927)), and Lane (*Jour. Ind. Eng. Chem.*, **17**, 924 (1925)) but modified by adding 2°F to all temperatures below 0°F in accordance with the suggestion of the Procter and Gamble Co.

**TABLE 5.13** Compositions of Aqueous Antifreeze Solutions (*Continued*)

| 14                  | 1.104                        | − 9.94         | 14.1 |                     |                              |                |        |

\* Saturation temperatures of sodium chloride dihydrate; at these temperatures NaCl · 2H<sub>2</sub>O separates leaving the brine of the eutectic composition (E).

5.4.1 Propylene Glycol–Glycerol

Propylene glycol, a satisfactory antifreeze with the advantage of being nontoxic, can be combined with glycerol, also an efficient nontoxic antifreeze, to give a mixture that can be tested for freezing point with an ethylene glycol (Prestone) hydrometer. A mixture of 70% propylene glycol and 30% glycerol (% by weight of water-free materials), when diluted, can be tested on the standard instrument used for ethylene glycol solutions.

5.5 DENSITY AND SPECIFIC GRAVITY

TABLE 5.14 Density of Mercury and Water

The density of mercury and pure air-free water under a pressure of 101 325 Pa(1 atm) is given in units of grams per cubic centimeter ( $\text{g} \cdot \text{cm}^{-3}$ ). For mercury, the values are based on the density at 20°C being  $13.545\,884\,\text{g} \cdot \text{cm}^{-3}$ . Water attains its maximum density of  $0.999\,973\,\text{g} \cdot \text{cm}^{-3}$  at 3.98°C. For water, the temperature ( $t_m$ , °C) of maximum density at different pressures ( $p$ ) in atmospheres is given by

$$t_m = 3.98 - 0.0225(p - 1)$$

| Density<br>of water | Temp.,<br>°C | Density<br>of mercury | Density<br>of water | Temp.,<br>°C | Density<br>of mercury |

**TABLE 5.15** Specific Gravity of Air at Various Temperatures

The table below gives the weight in grams  $\times 10^4$  of 1 mL of air at 760 mm of mercury pressure and at the temperature indicated. Density in grams per milliliter is the same as the specific gravity referred to water at 4°C as unity. To convert to density referred to air at 70°F as unity, divide the values below by 12.00.

| t°C. | Sp.Gr. $\times 10^4$ | t°C. | Sp.Gr. $\times 10^4$ | t°C. | Sp.Gr. $\times 10^4$ | t°C. | Sp.Gr. $\times 10^4$ |
|------|----------------------|------|----------------------|------|----------------------|------|----------------------|
| −25  | 14.240               | 15   | 12.255               | 60   | 10.596               | 140  | 8.541                |

**5.5.1 Density of Moist Air**

The density of moist air depends upon the temperature, the humidity, and the barometric pressure. It is expressed by the equation

$$d_t = D_t \times \frac{P - 0.3783e}{760}$$

where  $d_t$  is the density of the moist air at the temperature  $t$ ;  $D_t$  is the density of dry air at the temperature  $t$  (see Table 5.15, Specific Gravity of Air at Various Temperatures);  $P$  is the height of the barometer after correction and reduction to standard conditions, and is expressed in millimeters of mercury (see Sec. 2.1.3, Barometry and Barometric Corrections);  $e$  is the vapor pressure of water at the temperature of the dew point and is expressed in millimeters of mercury (see Table 5.6, Vapor Pressure of Water).

*Example.* To find the density of moist air at a temperature of 20°C, with a dew point of 10°C, and a corrected barometric pressure of 750 mm.

Reference to Table 5.15 shows that  $D$  at 20°C is equal to 0.001 204 6 g/mL. Reference to Table 5.6 shows that at 10°C (the temperature of the dew point)  $e$  is equal to 9.209 mm. Therefore,

$$\begin{aligned} d &= 0.001\,204\,6 \times \frac{750 - (0.3783 \times 9.209)}{760} \\ &= 0.001\,183\,2 \text{ g/mL} = 1.1832 \text{ g/L} \end{aligned}$$

## 5.5.2 Specific Gravity Corrections for the Buoyant Effect of Air

### 5.5.2.1 Determinations Made with a Pycnometer

$$\begin{aligned} D_{\text{vac}} &= \frac{W_2}{W_1} d - 0.0012 \left( \frac{W_2 d}{W_1} - 1 \right) \\ S_{\text{vac}} &= \frac{W_2}{W_1} - 0.0012 \left( \frac{W_2}{W_1} - 1 \right) \end{aligned}$$

where  $D_{\text{vac}}$  = density of the liquid in grams per milliliter at  $t^\circ\text{C}$  corrected for the buoyant effect of air

$W_1$  = weight in air of the water required to fill the pycnometer at  $t^\circ\text{C}$

$W_2$  = weight in air of the liquid required to fill the pycnometer at  $t^\circ\text{C}$

$d$  = density of water in grams per milliliter at  $t^\circ\text{C}$

$S_{\text{vac}}$  = specific gravity of the liquid at  $t^\circ\text{C}$  referred to water at  $t^\circ\text{C}$  corrected for the buoyant effect of air

When the weight of the water is determined at a temperature of  $t^\circ\text{C}$ , and that of the liquid at a different temperature  $t'$ , the equations above are modified as follows:

$$\begin{aligned} D_{\text{vac}} &= \frac{W_2}{W_1} d - 0.0012 \left( \frac{W_2}{W_1} d - 1 \right) + 0.000\,026 (t' - t^\circ) \left( \frac{W_2}{W_1} d \right) \\ S_{\text{vac}} &= \frac{W_2}{W_1} - 0.0012 \left( \frac{W_2}{W_1} - 1 \right) + 0.000\,026 (t' - t^\circ) \left( \frac{W_2}{W_1} \right) \end{aligned}$$

**5.5.2.2 Determinations Made with a Plummet or Sinkers.** The equations above may also be used when the density is determined with plummet or sinker, but in this case

$W_1$  = weight of the plummet in air minus its weight in water

$W_2$  = weight of the plummet in air minus its weight in the liquid

5.6 VISCOSITY, SURFACE TENSION, DIELECTRIC CONSTANT, DIPOLE MOMENT, AND REFRACTIVE INDEX

TABLE 5.16 Viscosity and Surface Tension of Various Organic Substances

For the majority of substances the dependence of the surface tension  $\gamma$  on the temperature can be given as:

$$\gamma = a - bt$$

where  $a$  and  $b$  are constants and  $t$  is the temperature in degrees Celsius. In the SI system the surface tensions are expressed in  $\text{mN} \cdot \text{m}^{-1}$  ( $= \text{dyn} \cdot \text{cm}^{-1}$ ).

A compilation of some 2200 liquid compounds has been prepared by J. J. Jasper, *J. Phys. Chem. Reference Data* 1:841 (1972).

The SI unit of viscosity is pascal-second ( $\text{Pa} \cdot \text{s}$ ) or newton-second per meter squared ( $\text{N} \cdot \text{s} \cdot \text{m}^{-2}$ ). Values tabulated are  $\text{mN} \cdot \text{s} \cdot \text{m}^{-2}$  ( $=$  centipoise, cP). The temperature in degrees Celsius at which the viscosity of a substance was measured is shown in parentheses after the value.

| Substance                | Surface tension,<br>$\text{mN} \cdot \text{m}^{-1}$ |           | Liquid range, $^{\circ}\text{C}$           | Viscosity, $\text{mN} \cdot \text{s} \cdot \text{m}^{-2}$ |
|--------------------------|-----------------------------------------------------|-----------|--------------------------------------------|-----------------------------------------------------------|
|                          | $a$                                                 | $b$       |                                            |                                                           |

**TABLE 5.17** Dielectric Constant (Permittivity) and Dipole Moment of Various Organic Substances

The temperature in degrees Celsius at which the dielectric constant and dipole moment were measured is shown in this table in parentheses after the value. In some cases, the dipole moment was determined with the substance dissolved in a solvent, and the solvent used is also shown in parentheses after the temperature.

The dielectric constant (permittivity) tabulated is the relative dielectric constant, which is the ratio of the actual electric displacement to the electric field strength when an external field is applied to the substance, which is the ratio of the actual dielectric constant to the dielectric constant of a vacuum. The table gives the static dielectric constant  $\epsilon$ , measured in static fields or at relatively low frequencies where no relaxation effects occur.

The dipole moment is given in debye units D. The conversion factor to SI units is  $1 \text{ D} = 3.33564 \times 10^{-30} \text{ C} \cdot \text{m}$ .

Alternative names for entries are listed in Table 1.15 at the bottom of each double page.

#### List of Abbreviations

|                   |            |
|-------------------|------------|
| B, benzene        | g, gas     |
| C, $\text{CCl}_4$ | Hx, hexane |
| cHex, cyclohexane | lq, liquid |
| D, 1,4-dioxane    |            |

| Substance                                           | Dielectric constant, $\epsilon$   | Dipole moment, D             |
|-----------------------------------------------------|-----------------------------------|------------------------------|
| Acetaldehyde                                        | 21.8 (10), 21.0 (18)              | 2.75                         |
| Acetaldehyde oxime                                  | 4.70 (25)                         | 0.830 (20, lq), 0.90 (25, B) |
| Acetamide                                           | 67.6 (91)                         | 3.76                         |
| Acetanilide                                         |                                   | 3.65 (25, B)                 |
| Acetic acid                                         | 6.20 (20)                         | 1.70                         |
| Acetic anhydride                                    | 23.3 (0), 22.45 (20)              | 2.8                          |
| Acetone                                             | 21.0 (20), 20.7 (25), 17.6 (56)   | 2.88                         |
| Acetonitrile                                        | 36.64 (20), 26.6 (82)             | 3.924                        |
| Acetophenone                                        | 17.44 (25), 8.64 (202)            | 3.02                         |
| ( $\pm$ )- <i>erythro</i> -2-Acetoxy-2-bromo-butane | 7.268 (25)                        |                              |
| ( $\pm$ )- <i>threo</i> -2-Acetoxy-2-bromobutane    | 7.414 (25)                        |                              |
| Acetyl bromide                                      | 16.2 (20)                         | 2.43 (20, B)                 |
| Acetyl chloride                                     | 16.9 (2), 15.8 (22)               | 2.72                         |
| Acetylene                                           | 2.484 (−77)                       |                              |
| Acrylonitrile                                       | 33.0 (20)                         | 3.87                         |
| Allene                                              | 2.025 (−4)                        |                              |
| Allylamine                                          |                                   | 1.2                          |
| Allyl alcohol                                       | 19.7 (20)                         | 1.61                         |
| Allyl isocyanate                                    | 15.15 (15)                        |                              |

**TABLE 5.18** Viscosity, Dielectric Constant, Dipole Moment, and Surface Tension of Selected Inorganic Substances

For the majority of compounds the dependence of the surface tension  $\gamma$  on the temperature can be given as:

$$\gamma = a - bt$$

where  $a$  and  $b$  are constants and  $t$  is the temperature in degrees Celsius.  
The values of the dipole moment are for the gas phase.

| Substance                                    | Viscosity,<br>$\text{mN} \cdot \text{s} \cdot \text{m}^{-2}$     | Dielectric<br>constant, $\epsilon$                   | Dipole<br>moment, D | Surface tension,<br>$\text{mN} \cdot \text{m}^{-1}$ |                    |

### 5.6.1 Refractive Index

The refractive index  $n$  is the ratio of the velocity of light in a particular substance to the velocity of light in vacuum. Values reported refer to the ratio of the velocity in air to that in the substance saturated with air. Usually the yellow sodium doublet lines are used; they have a weighted mean of 589.26 nm and are symbolized by **D**. When only a single refractive index is available, approximate values over a small temperature range may be calculated using a mean value of 0.000 45 per degree for  $dn/dt$ , and remembering that  $n_D$  decreases with an increase in temperature. If a transition point lies within the temperature range, extrapolation is not reliable.

The *specific refraction*  $r_D$  is given by the Lorentz and Lorenz equation,

$$R_D = \frac{n_D^2 - 1}{n_D^2 + 2} \cdot \frac{1}{\rho}$$

where  $\rho$  is the density at the same temperature as the refractive index, and is independent of temperature and pressure. The molar refraction is equal to the specific refraction multiplied by the molecular weight. It is a more or less additive property of the groups or elements comprising the compound. A set of atomic refractions is given in Table 5.19; an extensive discussion will be found in Bauer, Fajans, and Lewin, in *Physical Methods of Organic Chemistry*, 3d ed., A. Weissberger (ed.), vol. 1, part II, chap. 28, Wiley-Interscience, New York, 1960.

The empirical Eykman equation

$$\frac{n_D^2 - 1}{n_D + 0.4} \cdot \frac{1}{\rho} = \text{constant}$$

offers a more accurate means for checking the accuracy of experimental densities and refractive indices, and for calculating one from the other, than does the Lorentz and Lorenz equation.

The refractive index of moist air can be calculated from the expression

$$(n - 1) \times 10^6 = \frac{103.49}{T} p_1 + \frac{177.4}{T} p_2 + \frac{86.26}{T} \left( 1 + \frac{5748}{T} \right) p_3$$

where  $p_1$  is the partial pressure of dry air (in mmHg),  $p_2$  is the partial pressure of carbon dioxide (in mmHg),  $p_3$  is the partial pressure of water vapor (in mmHg), and  $T$  is the temperature (in kelvins).

*Example:* 1-Propynyl acetate has  $n_D = 1.4187$  and density = 0.9982 at 20°C; the molecular weight is 98.102. From the Lorentz and Lorenz equation,

$$r_D = \frac{(1.4187)^2 + 1}{(1.4187)^2 + 2} \cdot \frac{1}{0.9982} = 0.2528$$

The molar refraction is

$$Mr_D = (98.102)(0.2528) = 24.80$$

From the atomic and group refractions in Table 5.19, the molar refraction is computed as follows:

|                |                 |
|----------------|-----------------|
| 6 H            | 6.600           |
| 5 C            | 12.090          |
| 1 C $\equiv$ C | 2.398           |
| 1 O(ether)     | 1.643           |
| 1 O(carbonyl)  | <u>2.211</u>    |
|                | $Mr_D = 24.942$ |

### 5.6.2 Surface Tension

The surface tension of a liquid,  $\gamma$ , is the force per unit length on the surface that opposes the expansion of the surface area. In the literature the surface tensions are expressed in  $\text{dyn} \cdot \text{cm}^{-1}$ ;  $1 \text{ dyn} \cdot \text{cm}^{-1} = 1 \text{ mN} \cdot \text{m}^{-1}$  in the SI system. For the large majority of compounds the dependence of the surface tension on the temperature can be given as

$$\gamma = a - bt$$

where  $a$  and  $b$  are constants and  $t$  is the temperature in degrees Celsius. The values of  $a$  and  $b$  given in Tables 5.16 and 5.18 can be used to calculate the values of surface tension for the particular compound within its liquid range. For example, the least-squares constants for acetic anhydride (liquid from  $-73$  to  $140^\circ\text{C}$ ) are 35.52 and 0.1436, respectively. At  $20^\circ\text{C}$ ,  $\gamma = 35.52 - 0.1436(20) = 32.64 \text{ dyn} \cdot \text{cm}^{-1}$ .

A compilation of data of some 2200 pure liquid compounds has been prepared by Jasper, *J. Phys. Chem. Reference Data* **1**:841 (1972).

### 5.6.3 Dipole Moments

The permanent dipole moment of an isolated molecule depends on the magnitude of the charge and on the distance separating the positive and negative charges. It is defined as

$$\mu = \left( \sum_i q_i r_i \right)$$

where the summation extends over all charges (electrons and nuclei) in the molecule. The numerical values of the dipole moment, expressed in the c.g.s. system of units, are in debye units, D, where  $1 \text{ D} = 10^{-18} \text{ esu of charge} \times \text{centimeters}$ . The conversion factor to SI units is

$$1 \text{ D} = 3.335\,64 \times 10^{-30} \text{ C} \cdot \text{m} \quad [\text{coulomb-meter}]$$

Tables 5.17 and 5.18 contain a selected group of compounds for which the dipole moment is given. An extensive collection of dipole moments (approximately 7000 entries) is contained in A. L. McClellan, *Tables of Experimental Dipole Moments*, W. H. Freeman, San Francisco, 1963. A critical survey of 500 compounds in the gas phase is given by Nelson, Lide, and Maryott, NSRDS-NBS 10, Washington, D.C., 1967.

### 5.6.4 Dielectric Constants

If two oppositely charged plates exist in a vacuum, there is a certain force of attraction between them, as stated by Coulomb's law:

$$F = \frac{1}{4\pi\epsilon_0} \cdot \frac{q_1 q_2}{\epsilon r^2}$$

where  $F$  is the force, in newtons, acting on each of the charges  $q_1$  and  $q_2$ ,  $r$  is the distance between the charges,  $\epsilon$  is the dielectric constant of the medium between the plates, and  $\epsilon_0$  is the permittivity of free space.  $q_1$ ,  $q_2$  are expressed in coulombs and  $r$  in meters. If another substance, such as a solvent, is in the space separating these charges (or ions in a solution), their attraction for each other is less. The dielectric constant is a measure of the relative effect a solvent has on the force with which two oppositely charged plates attract each other. The dielectric constant is a unitless number.

Dielectric constants for a selected group of inorganic and organic compounds are included in Tables 5.17 and 5.18. An extensive list has been compiled by Maryott and Smith, *National Bureau Standards Circular 514*, Washington, D.C., 1951.

For gases the values of the dielectric constant can be adjusted to somewhat different conditions of temperature and pressure by means of the equation

$$\frac{(\epsilon - 1)_{t,p}}{(\epsilon - 1)_{20^\circ, 1 \text{ atm}}} = \frac{p}{760[1 + 0.003\,411(t - 20)]}$$

where  $p$  is the pressure (in mmHg) and  $t$  is the temperature (in  $^\circ\text{C}$ ). The errors associated with this equation probably do not exceed 0.02% for gases between 10 and  $30^\circ\text{C}$  and for pressures between 700 and 800 mm. The dielectric constants of selected gases will be found in Table. 5.18.

### 5.6.5 Viscosity

The *dynamic viscosity*, or coefficient of viscosity,  $\eta$  of a Newtonian fluid is defined as the force per unit area necessary to maintain a unit velocity gradient at right angles to the direction of flow between two parallel planes a unit distance apart. The SI unit is pascal-second or newton-second per meter squared [ $\text{N} \cdot \text{s} \cdot \text{m}^{-2}$ ]. The c.g.s. unit of viscosity is the poise [P];  $1 \text{ cP} \equiv 1 \text{ mN} \cdot \text{s} \cdot \text{m}^{-2}$ . The dynamic viscosity decreases with the temperature approximately according to the equation:  $\log \eta = A + B/T$ . Values of  $A$  and  $B$  for a large number of liquids are given by Barrer, *Trans. Faraday Soc.* **39:48** (1943).

TABLE 5.21 Aqueous Glycerol Solutions

| % Weight glycerol | Grams per liter | Relative density 25°/25°C | Viscosity, mN · s · m <sup>-2</sup> |       |       |
|-------------------|-----------------|---------------------------|-------------------------------------|-------|-------|
|                   |                 |                           | 20°C                                | 25°C  | 30°C  |
| 100               | 1261            | 1.262 01                  | 1 495                               | 942   | 622   |
| 99                | 1246            | 1.259 45                  | 1 194                               | 772   | 509   |
| 98                | 1231            | 1.256 85                  | 971                                 | 627   | 423   |
| 97                | 1216            | 1.254 25                  | 802                                 | 521   | 353   |
| 96                | 1201            | 1.251 65                  | 659                                 | 434   | 296   |
| 95                | 1186            | 1.249 10                  | 543.5                               | 365   | 248   |
| 80                | 966.8           | 1.209 25                  | 61.8                                | 45.72 | 34.81 |
| 50                | 563.2           | 1.127 20                  | 6.032                               | 5.024 | 4.233 |
| 25                | 265.0           | 1.061 15                  | 2.089                               | 1.805 | 1.586 |
| 10                | 102.2           | 1.023 70                  | 1.307                               | 1.149 | 1.021 |

*Kinematic viscosity*  $\nu$  is the ratio of the dynamic viscosity to the density of a fluid. The SI unit is meter squared per second [m<sup>2</sup> · s<sup>-1</sup>]. The c.g.s. units are called stokes [cm<sup>2</sup> · s<sup>-1</sup>]; poises = stokes × density.

*Fluidity*  $\phi$  is the reciprocal of the dynamic viscosity.

The primary reference liquid for viscosity measurements is water. The absolute viscosity of water at 20°C is 1.0019 (±0.0003) mN · s · m<sup>-2</sup> (or centipoise), as determined by Swindells, Coe, and Godfrey, *J. Research Natl. Bur. Standards* **48**:1 (1952). The relative viscosity of water,  $\eta/\eta_{20^\circ}$ , is 0.8885 at 25°C, 0.7960 at 30°C, and 0.6518 at 40°C. Values at temperatures between 15 and 60°C are best represented by Cragoe’s equation:

$$\log \frac{\eta}{\eta_{20^\circ}} = \frac{1.2348(20 - t) - 0.001\,467(t - 20)^2}{t + 96}$$

The *Reynolds number* for flow in a tube is defined by  $d\bar{v}\rho/\eta$ , where  $d$  is the diameter of the tube,  $\bar{v}$  is the average velocity of the fluid along the tube,  $\rho$  is the density of the fluid, and  $\eta$  is its dynamic viscosity. At flow velocities corresponding with values of the Reynolds number of greater than 2000, turbulence is encountered.

TABLE 5.22 Aqueous Sucrose Solutions

| % Weight sucrose | Grams per liter | Relative density 20°/4°C | Viscosity, mN · s · m <sup>-2</sup> |       |       |
|------------------|-----------------|--------------------------|-------------------------------------|-------|-------|
|                  |                 |                          | 15°C                                | 20°C  | 25°C  |

| 30               | 338.1           | 1.127 0                  | 3.757                               | 3.187 | 2.735 |

5.7 COMBUSTIBLE MIXTURES

TABLE 5.23 Properties of Combustible Mixtures in Air

The *autoignition temperature* is the minimum temperature required for self-sustained combustion in the absence of an external ignition source. The value depends on specified test conditions. The *flammable (explosive) limits* specify the range of concentration of the vapor in air (in percent by volume) for which a flame can propagate. Below the lower flammable limit, the gas mixture is too lean to burn; above the flammable limit, the mixture is too rich. Additional compounds can be found in National Fire Protection Association, National Fire Protection Handbook, 14th ed., 1991.

For alternative nomenclature, see Table 1.15.

| Substance                       | Autoignition<br>temperature, °C | Flammable (explosive)<br>limits, percent by<br>volume of fuel (25°C,<br>760 mm) |       |
|---------------------------------|---------------------------------|---------------------------------------------------------------------------------|-------|
|                                 |                                 | Lower                                                                           | Upper |
| Acetaldehyde                    | 175                             | 4.0                                                                             | 60    |
| Acetanilide                     | 540                             |                                                                                 |       |
| Acetic acid, glacial            | 463                             | 4.0                                                                             | 19.9  |
| Acetic anhydride                | 316                             | 2.7                                                                             | 10.3  |

5.8 THERMAL CONDUCTIVITY

TABLE 5.24 Thermal Conductivities of Gases as a Function of Temperature

The coefficient  $k$ , expressed in  $\text{J} \cdot \text{sec}^{-1} \cdot \text{cm}^{-1} \cdot \text{K}^{-1}$ , is the quantity of heat in joules, transmitted per second through a sample one centimeter in thickness and one square centimeter in area when the temperature difference between the two sides is one degree kelvin (or Celsius). The tabulated values are in microjoules. To convert to microcalories, divide values by 4.184. To convert to  $\text{mW} \cdot \text{m}^{-1} \cdot \text{K}^{-1}$ , divide values by 10.

**TABLE 5.25** Liquid Thermal Conductivity of Various Substances

All values of thermal conductivity,  $k$ , are in millijoules  $\text{cm}^{-1} \cdot \text{s}^{-1} \cdot \text{K}^{-1}$ . To convert to  $\text{mJ} \cdot \text{cm}^{-1} \cdot \text{s}^{-1} \cdot \text{K}^{-1}$  into  $\text{mW} \cdot \text{m}^{-1} \cdot \text{K}^{-1}$ , divide by 10.

| Substance                     | Thermal conductivity in $\text{mJ} \cdot \text{cm}^{-1} \cdot \text{s}^{-1} \cdot \text{K}^{-1}$ |                     |                    |                     |                    |                     |       |

TABLE 5.26 Thermal Conductivity of Various Solids

All values of thermal conductivity,  $k$ , are in millijoules  $\text{cm}^{-1} \cdot \text{s}^{-1} \cdot \text{K}^{-1}$ . To convert to  $\text{mW} \cdot \text{m}^{-1} \cdot \text{K}^{-1}\text{m}$ , divide values by 10. For values in millicalories, divide by 4.184.

**TABLE 5.29** Van der Waals' Constants for Gases

The van der Waals' equation of state for a real gas is:

$$\left(P + \frac{n^2 a}{V^2}\right)(V - nb) = nRT \quad \text{for } n \text{ moles}$$

where  $P$  is the pressure,  $V$  the volume (in liters per mole = 0.001 m<sup>3</sup> per mole in the SI system),  $T$  the temperature (in degrees Kelvin),  $n$  the amount of substance (in moles), and  $R$  the gas constant. To use the values of  $a$  and  $b$  in the table,  $P$  must be expressed in the same units as in the gas constant. Thus, the pressure of a standard atmosphere may be expressed in the SI system as follows:

$$1 \text{ atm} = 101,325 \text{ N} \cdot \text{m}^{-2} = 101,325 \text{ Pa} = 1.01325 \text{ bar}$$

The appropriate value for the gas constant is:

$$0.083\,144\,1 \text{ L} \cdot \text{bar} \cdot \text{K}^{-1} \cdot \text{mol}^{-1} \quad \text{or} \quad 0.082\,056 \text{ L} \cdot \text{atm} \cdot \text{K}^{-1} \cdot \text{mol}^{-1}$$

The van der Waals' constants are related to the critical temperature and pressure,  $t_c$  and  $P_c$ , in Table 6.5 by:

$$a = \frac{27 R^2 T_c^2}{64 P_c} \quad \text{and} \quad b = \frac{RT_c}{8 P_c}$$

| Substance                  | $a, \text{L}^2 \cdot \text{bar} \cdot \text{mol}^{-2}$ | $b, \text{L} \cdot \text{mol}^{-1}$ |

### 5.9.1 Some Physical Chemistry Equations for Gases

A number of physical chemistry relationships, not enumerated in other sections (*see* Index), will be discussed in this section.

*Boyle's law* states that the volume of a given quantity of a gas varies inversely as the pressure, the temperature remaining constant. That is,

$$V = \frac{\text{constant}}{P} \quad \text{or} \quad PV = \text{constant}$$

A convenient form of the law, true strictly for ideal gases, is

$$P_1 V_1 = P_2 V_2$$

*Charles' law*, also known as *Gay-Lussac's law*, states that the volume of a given mass of gas varies directly as the absolute temperature if the pressure remains constant, that is,

$$\frac{V}{T} = \text{constant}$$

Combining the laws of Boyle and Charles into one expression gives

$$\frac{P_1 V_1}{T_1} = \frac{P_2 V_2}{T_2}$$

In terms of moles, *Avogadro's hypothesis* can be stated: The same volume is occupied by one mole of any gas at a given temperature and pressure. The number of molecules in one mole is known as the *Avogadro number constant*  $N_A$ .

The behavior of all gases that obey the laws of Boyle and Charles, and Avogadro's hypothesis, can be expressed by the ideal gas equation:

$$PV = nRT$$

where  $R$  is called the *gas constant* and  $n$  is the number of moles of gas. If pressure is written as force per unit area and the volume as area times length, then  $R$  has the dimensions of energy per degree per mole— $8.314 \text{ J} \cdot \text{K}^{-1} \cdot \text{mol}^{-1}$  or  $1.987 \text{ cal} \cdot \text{K}^{-1} \cdot \text{mol}^{-1}$ .

*Dalton's law of partial pressures* states that the total pressure exerted by a mixture of gases is equal to the sum of the pressures which each component would exert if placed separately into the container:

$$P_{\text{total}} = p_1 + p_2 + p_3 + \cdots$$

There are two ways to express the fraction which one gaseous component contributes to the total mixture: (1) the pressure fraction,  $p_i/P_{\text{total}}$ , and (2) the mole fraction,  $n_i/n_{\text{total}}$ .

### 5.9.1.1 Equations of State (PVT Relations for Real Gases)

1. *Virial equation* represents the experimental compressibility of a gas by an empirical equation of state:

$$PV = A_p + B_p P + C_p P^2 + \cdots$$

or

$$PV = A_v + B_v V + \frac{C_v}{V^2} + \cdots$$

where  $A, B, C, \dots$  are called the virial coefficients and are a function of the nature of the gas and the temperature.

2. *Van der Waals' equation*:

$$\left( P + \frac{an^2}{V^2} \right) (V - nb) = nRT$$

where the term  $an^2/V^2$  is the correction for intermolecular attraction among the gas molecules and the  $nb$  term is the correction for the volume occupied by the gas molecules. The constants  $a$  and  $b$  must be fitted for each gas from experimental data (Table 5.28); consequently the equation is semiempirical. The constants are related to the critical-point constants (Table 6.5) as follows:

$$a = 3P_c V_c^2$$

$$b = \frac{V_c}{3}$$

$$R = \frac{8P_c V_c}{3T_c}$$

Substitution into van der Waals' equation and rearrangement leads to only the terms  $P/P_c$ ,  $V/V_c$ , and  $T/T_c$ , which are called the reduced variables  $P_R$ ,  $V_R$ , and  $T_R$ . For 1 mole of gas,

$$\left( P_R + \frac{3}{V_R^2} \right) \left( V_R - \frac{1}{3} \right) = \frac{8}{3} T_R$$

3. *Berthelot's equation of state*, used by many thermodynamicists, is

$$PV = nRT \left[ 1 + \frac{9}{128} \frac{P T_c}{P_c T} \left( 1 - 6 \frac{T_c^2}{T^2} \right) \right]$$

This equation requires only knowledge of the critical temperature and pressure for its use and gives accurate results in the vicinity of room temperature for unassociated substances at moderate pressures.

### 5.9.1.2 Properties of Gas Molecules

**Vapor Density.** Substitution of the Antoine vapor-pressure equation for its equivalent  $\log P$  in the ideal gas equation gives

$$\log \rho_{\text{vap}} = \log M - \log R - \log (t + 273.15) + A - \frac{B}{t + C}$$

where  $\rho_{\text{vap}}$  is the vapor density in  $\text{g} \cdot \text{mL}^{-1}$  at  $t^\circ\text{C}$ ,  $M$  is the molecular weight,  $R$  is the gas constant, and  $A$ ,  $B$ , and  $C$  are the constants of the Antoine equation for vapor pressure. Since this equation is based on the ideal gas law, it is accurate only at temperatures at which the vapor of any specific compound follows this law. This condition prevails at reduced temperatures ( $T_R$ ) of about 0.5 K.

**Velocities of Molecules.** The mean square velocity of gas molecules is given by

$$\overline{u^2} = \frac{3kT}{m} = \frac{3RT}{M}$$

where  $k$  is Boltzmann's constant and  $m$  is the mass of the molecule.

The mean velocity is given by

$$\bar{u} = \left( \frac{8\overline{u^2}}{3\pi} \right)^{1/2}$$

**Viscosity.** On the assumption that molecules interact like hard spheres, the viscosity of a gas is

$$\eta = \left( \frac{5}{16\sigma^2} \right) \left( \frac{mkT}{\pi} \right)^{1/2}$$

where  $\sigma$  is the molecular diameter.

**Mean Free Path.** The mean free path of a gas molecule  $l$  and the mean time between collisions  $\tau$  are given by

$$l = \frac{m}{\pi\rho\sigma^2\sqrt{2}}$$

$$\tau = \frac{1}{\bar{u}} = \frac{4\eta}{5P}$$

**Graham's Law of Diffusion.** The rates at which gases diffuse under the same conditions of temperature and pressure are inversely proportional to the square roots of their densities:

$$\frac{r_1}{r_2} = \left( \frac{\rho_2}{\rho_1} \right)^{1/2}$$

Since  $\rho = MP/RT$  for an ideal gas, it follows that

$$\frac{r_1}{r_2} = \left( \frac{M_2}{M_1} \right)^{1/2}$$

*Henry's Law.* The solubility of a gas is directly proportional to the partial pressure exerted by the gas:

$$p_i = k\alpha_i$$

*Joule-Thompson Coefficient for Real Gases.* This expresses the change in temperature with respect to change in pressure at constant enthalpy:

$$\mu_\pi = \left( \frac{\partial T}{\partial P} \right)_H$$

### 6.1 ENTHALPIES AND GIBBS ENERGIES OF FORMATION, ENTROPIES, AND HEAT CAPACITIES

---

The tables in this section contain values of the enthalpy and Gibbs energy of formation, entropy, and heat capacity at 298.15 K (25°C). No values are given in these tables for metal alloys or other solid solutions, for fused salts, or for substances of undefined chemical composition.

The physical state of each substance is indicated in the column headed “State” as crystalline solid (c), liquid (lq), or gaseous (g). Solutions in water are listed as aqueous (aq).

The values of the thermodynamic properties of the pure substances given in these tables are, for the substances in their standard states, defined as follows: For a pure solid or liquid, the standard state is the substance in the condensed phase under a pressure of 1 atm (101 325 Pa). For a gas, the standard state is the hypothetical ideal gas at unit fugacity, in which state the enthalpy is that of the real gas at the same temperature and at zero pressure.

The values of  $\Delta_f H^\circ$  and  $\Delta_f G^\circ$  that are given in the tables represent the change in the appropriate thermodynamic quantity when one mole of the substance in its standard state is formed, isothermally at the indicated temperature, from the elements, each in its appropriate standard reference state. The standard reference state at 25°C for each element has been chosen to be the standard state that is thermodynamically stable at 25°C and 1 atm pressure. The standard reference states are indicated in the tables by the fact that the values of  $\Delta_f H^\circ$  and  $\Delta_f G^\circ$  are exactly zero.

The values of  $S^\circ$  represent the virtual or “thermal” entropy of the substance in the standard state at 298.15 K (25°C), omitting contributions from nuclear spins. Isotope mixing effects are also excluded except in the case of the  $^1\text{H}$ — $^2\text{H}$  system.

Solutions in water are designated as aqueous, and the concentration of the solution is expressed in terms of the number of moles of solvent associated with 1 mol of the solute. If no concentration is indicated, the solution is assumed to be dilute. The standard state for a solute in aqueous solution is taken as the hypothetical ideal solution of unit molality (indicated as std. state or ss). In this state

the partial molal enthalpy and the heat capacity of the solute are the same as in the infinitely dilute real solution.

For some tables the uncertainty of entries is indicated within parentheses immediately following the value; viz., an entry 34.5(4) implies  $34.5 \pm 0.4$  and an entry 34.5(12) implies  $34.5 \pm 1.2$ .

### 6.1.1 Some Thermodynamic Relations

**6.1.1.1 Enthalpy of Formation.** Once standard enthalpies are assigned to the elements, it is possible to determine standard enthalpies for compounds. For the reaction:

Since the elements are in their standard states, the enthalpy change for the reaction is equal to the standard enthalpy of  $\text{CO}_2$  less the standard enthalpies of C and  $\text{O}_2$ , which are zero in each instance. Thus,

$$\Delta_f H^\circ = -393.51 - 0 - 0 = -393.51 \text{ kJ} \quad (6.2)$$

Tables of enthalpies, such as Tables 6.1 and 6.3, can be used to determine the enthalpy for any reaction at 1 atm and 298.15 K involving the elements and any of the compounds appearing in the tables.

The solution of 1 mole of HCl gas in a large amount of water (infinitely dilute real solution) is represented by:

The heat evolved in the reaction is  $\Delta H^\circ = -74.84 \text{ kJ}$ . With the value of  $\Delta_f H^\circ$  from Table 6.3, one has for the reaction:

$$\Delta_f H^\circ = \Delta_f H^\circ[\text{H}^+(\text{aq})] + \Delta_f H^\circ[\text{Cl}^-(\text{aq})] - \Delta_f H^\circ[\text{HCl}(\text{g})] \quad (6.4)$$

for the standard enthalpy of formation of the pair of ions  $\text{H}^+$  and  $\text{Cl}^-$  in aqueous solution (standard state,  $m = 1$ ). To obtain the  $\Delta_f H^\circ$  values for individual ions, the enthalpy of formation of  $\text{H}^+(\text{aq})$  is arbitrarily assigned the value zero at 298.15 K. Thus, from Eq. (6.4):

$$\Delta_f H^\circ[\text{Cl}^-(\text{aq})] = -74.84 + (-92.31) = -167.15 \text{ kJ}$$

With similar data from Tables 6.1 and 6.3, the enthalpies of formation of other ions can be determined. Thus, from the  $\Delta_f H^\circ[\text{KCl}(\text{aq, std. state, } m = 1 \text{ or aq, ss})]$  of  $-419.53 \text{ kJ}$  and the foregoing value for  $\Delta_f H^\circ[\text{Cl}^-(\text{aq, ss})]$ :

$$\begin{aligned} \Delta_f H^\circ[\text{K}^+(\text{aq, ss})] &= \Delta_f H^\circ[\text{KCl}(\text{aq, ss})] - \Delta_f H^\circ[\text{Cl}^-(\text{aq, ss})] \\ &= -419.53 - (-167.15) = -252.38 \text{ kJ} \end{aligned} \quad (6.5)$$

**6.1.1.2 Enthalpy of Vaporization (or Sublimation)** When the pressure of the vapor in equilibrium with a liquid reaches 1 atm, the liquid boils and is completely converted to vapor on absorption of the enthalpy of vaporization  $\Delta H_v$  at the normal boiling point  $T_b$ . A rough empirical relationship between the normal boiling point and the enthalpy of vaporization (*Trouton's rule*) is:

$$\frac{\Delta H_v}{T_b} = 88 \text{ J} \cdot \text{mol}^{-1} \cdot \text{K}^{-1} \quad (6.6)$$

It is best applied to nonpolar liquids which form unassociated vapors.

To a first approximation, the enthalpy of sublimation  $\Delta H_s$  at constant temperature is:

$$\Delta H_s = \Delta H_m + \Delta H_v \quad (6.7)$$

where  $\Delta H_m$  is the enthalpy of melting.

The *Clapeyron* equation expresses the dynamic equilibrium existing between the vapor and the condensed phase of a pure substance:

$$\frac{dP}{dT} = \frac{\Delta H_v}{T\Delta V} \quad (6.8)$$

where  $\Delta V$  is the volume increment between the vapor phase and the condensed phase. If the condensed phase is solid, the enthalpy increment is that of sublimation.

Substitution of  $V = RT/P$  into the foregoing equation and rearranging gives the *Clausius-Clapeyron* equation,

$$\frac{dP}{P dT} = \frac{\Delta H_v}{RT^2} \quad (6.9)$$

or

$$\Delta H_v = -R \frac{d(\ln P)}{1/T} \quad (6.10)$$

which may be used for calculating the enthalpy of vaporization of any compound provided its boiling point at any pressure is known. If an Antoine equation is available (such as Eq. (5.1), page 5.30), differentiation and insertion into the foregoing equation gives:

$$\Delta H_v = \frac{4.5757T^2B}{(T + C - 273.15)^2} \quad (6.11)$$

Inclusion of a compressibility factor into the foregoing equation, as suggested by the *Haggemacher* equation improves the estimate of  $\Delta H_v$ :

$$\Delta H_v = \frac{RT^2}{P} \left( \frac{dP}{dT} \right) \left( 1 - \frac{T_c^3 P}{T^3 P_c} \right)^{1/2} \quad (6.12)$$

where  $T_c$  and  $P_c$  are critical constants (Table 6.5). Although critical constants may be unknown, the compressibility factor is very nearly constant for all compounds belonging to the same family, and an estimate can be deduced from a related compound whose critical constants are available.

**6.1.1.3 Heat Capacity (or Specific Heat)** The temperature dependence of the heat capacity is complex. If the temperature range is restricted, the heat capacity of any phase may be represented adequately by an expression such as:

$$C_p = a + bT + cT^2 \quad (6.13)$$

in which  $a$ ,  $b$ , and  $c$  are empirical constants. These constants may be evaluated by taking three pieces of data:  $(T_1, C_{p,1})$ ,  $(T_2, C_{p,2})$ , and  $(T_3, C_{p,3})$ , and substituting in the following expressions:

$$\frac{C_{p,1}}{(T_1 - T_2)(T_1 - T_3)} + \frac{C_{p,2}}{(T_2 - T_1)(T_2 - T_3)} + \frac{C_{p,3}}{(T_3 - T_2)(T_3 - T_1)} = c \quad (6.14)$$

$$\frac{C_{p,1} - C_{p,2}}{T_1 - T_2} - [(T_1 + T_2)c] = b \quad (6.15)$$

$$(C_{p,1} - bT_1) - cT_1^2 = a \quad (6.16)$$

Smoothed data presented at rounded temperatures, such as are available in Tables 6.2 and 6.4, plus the  $C_p^\circ$  values at 298 K listed in Table 6.1 and 6.3, are especially suitable for substitution in the foregoing parabolic equations. The use of such a parabolic fit is appropriate for interpolation, but data extrapolated outside the original temperature range should not be sought.

**6.1.1.4 Enthalpy of a System** The enthalpy increment of a system over the interval of temperature from  $T_1$  to  $T_2$ , under the constraint of constant pressure, is given by the expression:

$$H_2 - H_1 = \int_{T_1}^{T_2} C_p dT \quad (6.17)$$

The enthalpy over a temperature range that includes phase transitions, melting, and vaporization, is represented by:

$$\begin{aligned} H_2 - H_1 = & \int_{T_1}^{T_2} C_{p(c,II)} dT + \Delta H_t + \int_{T_1}^{T_m} C_{p(c,I)} dT + \Delta H_m \\ & + \int_{T_m}^{T_b} C_{p(1q)} dT + \Delta H_v + \int_{T_b}^{T_2} C_{p(g)} dT \end{aligned} \quad (6.18)$$

Integration of heat capacities, as expressed by Eq. (6.13), leads to:

$$\Delta H = a(T_2 - T_1) + \frac{b(T_2^2 - T_1^2)}{2} + \frac{c(T_2^3 - T_1^3)}{3} \quad (6.19)$$

**6.1.1.5 Entropy** In the physical change of state,

$$\Delta S_m = \frac{\Delta H_m}{T_m} \quad (6.20)$$

is the entropy of melting (or fusion),

$$\Delta S_v = \frac{\Delta H_v}{T_b} \quad (6.21)$$

is the entropy of vaporization, and

$$\Delta S_s = \frac{\Delta H_s}{T_s} \quad (6.22)$$

is the entropy of sublimation.

A general expression for the entropy of a system, involving any phase transitions, is

$$S_2 - S_1 = \int_{T_1}^{T_i} \frac{C_p(c, \text{II})}{T} dT + \frac{\Delta H_t}{T} + \int_{T_b}^{T_m} \frac{C_p(c, \text{I})}{T} dT + \frac{\Delta H_m}{T} \\ + \int_{T_m}^{T_b} \frac{C_p(1q)}{T} dT + \frac{\Delta H_v}{T} + \int_{T_b}^{T_m} \frac{C_p(g)}{T} dT \quad (6.23)$$

If  $C_p$  is independent of temperature,

$$\Delta S = C_p (\ln T_2 - \ln T_1) = 2.303 C_p \log \frac{T_2}{T_1} \quad (6.24)$$

If the heat capacities change with temperature, an empirical equation like Eq. (6.13) may be inserted in Eq. (6.23) before integration. Usually the integration is performed graphically from a plot of either  $C_p/T$  versus  $T$  or  $C_p$  versus  $\ln T$ .
